## Very Fast, Complete 10- or 12-Bit A/D Converters

 AD578/AD579FEATURES
Performance
Complete 12-Bit A/D Converter with Reference and Clock
Fast Conversion: $3 \boldsymbol{\mu s}$ (max)
Buried Zener Reference for Long Term Stability and
Low Gain T.C.: $\pm \mathbf{3 0} \mathbf{~ p p m} /{ }^{\circ} \mathrm{C} \max (A D 578)$
$\pm 40 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$ max (AD579)
Max Nonlinearity: $< \pm \mathbf{0 . 0 1 2 \%}$
No Missing Codes Over Temperature
Low Power: 555 mW (AD578); 775 mW (AD579)
Available to MIL-STD-883

## Versatility

Positive-True Parallel or Serial Logic Outputs Short Cycle Capability
Precision +10 V Reference for External Applications
Adjustable Internal Clock
"Z" Models for $\pm 12 \mathrm{~V}$ Supplies

## GENERAL DESCRIPTION

The AD578 and AD579 are high speed 12-bit and 10-bit successive approximation analog-to-digital converters that include internal clock, reference, and comparator. Their hybrid design utilizes MSI digital and linear ICs in conjunction with a 12 -bit or 10 -bit monolithic, monotonic DAC to provide superior performance and versatility with IC size, price, and reliability.
Important performance characteristics of the AD578 include $\pm 1 / 2 \mathrm{LSB}_{12}$ linearity error maximum at $+25^{\circ} \mathrm{C}$, maximum gain tempco of $\pm 30 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$, and maximum conversion time of $3 \mu \mathrm{~s}$ at a typical power dissipation of 555 mW . The 10-bit AD579 provides $\pm 1 / 2 \mathrm{LSB}_{10}$ maximum linearity error at $1.8 \mu \mathrm{~s}$ maximum, and 775 mW typical $\mathrm{P}_{\mathrm{D}}$.
Both the AD578 and AD579 include scaling resistors that provide analog input signal ranges of $\pm 5 \mathrm{~V}, \pm 10 \mathrm{~V}$, and 0 to +10 V . Both are contained in 32-pin ceramic side-brazed DIP packages, and are available with MIL-STD-883 Class B processing.

REV. A

FUNCTIONAL BLIOCK DIAGRAM

## PRODUCT HIGHLIGHTS

1. Both are complete analog-to-digital converters. No external components are required to perform a conversion.
2. The fast conversion rates $-3 \mu \mathrm{~s}$ for the AD578, and $1.8 \mu \mathrm{~s}$ for the AD579-make them ideal candidates for high speed data acquisition systems requiring high throughput.
3. The internal buried Zener reference is laser trimmed to high initial accuracy and low T.C. and is available externally.
4. Precision thin film scaling resistors on the DAC provide for excellent thermal tracking.
5. Short cycle and external clock capabilities are provided for applications requiring faster conversion speeds and/or lower resolution.

## AD578/AD579

## ORDERING GUIDE ${ }^{1}$

## THEORY OF OPERATION

The AD578 is a complete pretrimmed 12-bit A/D converter which requires no external components to provide the successive-approximation analog-to-digital conversion function. A block diagram of the AD578 is shown in Figure 1.

Figure 1. AD578/AD579 Functional Block Diagram and Pinout

When the control section is commanded to initiate a conversion it enables the clock and resets the successive-approximation reg ister (SAR). The SAR, timed by the clock, sequences through the conversion cycle and returns an end-of-convert flag to the control section. The control section disables the clock and
brings the output status flag low. The data bits are valid on the falling edge of the clock pulse starting with $t_{1}$ and ending with $\mathrm{t}_{12}$ (Figure 2), and accurately represent the input signal to within $\pm 1 / 2$ LSB.

Figure 2a. AD578 $3 \mu \mathrm{~s}$ Timing Diagram

## AD578/AD579

The temperature-compensated buried Zener reference provides the primary voltage reference to the DAC and guarantees excel lent stability with both time and temperature. The reference is trimmed to 10.00 volts $\pm 1.0 \%$, it is buffered and can supply up to 1.0 mA to an external load in addition to the current required to drive the reference input resistor $(0.5 \mathrm{~mA})$ and bipolar offset resistor ( 1 mA ). The thin-film application resistors are trimmed to match the full scale output current of the DAC. There are two $5 \mathrm{k} \Omega$ input scaling resistors to allow either a 10 volt or 20
volt span. The $10 \mathrm{k} \Omega$ bipolar offset resistor is grounded for uni polar operation or connected to the 10 volt reference for bipolar operation.

## UNIPOLAR CALIBRATION

The AD578/AD579 is intended to have a nominal $1 / 2$ LSB off set so that the exact analog input for a given code will be in the middle of that code (halfway between the transitions to the codes above and below it). Thus, when properly calibrated, the first transition (from 000000000000 to 000000000001 ) will occur for an input level of $+1 / 2$ LSB.
If $\operatorname{Pin} 26$ is connected to $\operatorname{Pin} 30$, the unit will behave in this manner, within specifications. Refer to Table I, Table II, and Figure 3 for further clarification. If the offset trim (R1) is used, it should be trimmed as above, although a different offset can be set for a particular system requirement. This circuit will give approximately $\pm 25 \mathrm{mV}$ of offset trim range.
The full scale trim is done by applying a signal $11 / 2$ LSB below the nominal full scale. Trim R2 to give the last transition (1111 11111110 to 11111111111 ).

## BIPOLAR OPERATION

The connections for bipolar ranges are shown in Figure 4.
Again, as for the unipolar ranges, if the offset and gain specifications are sufficient the $100 \Omega$ trimmer shown can be replaced by a $50 \Omega \pm 1 \%$ fixed resistor. The analog input is applied as for the unipolar ranges. Bipolar calibration is similar to unipolar calibration. First, a signal $1 / 2$ LSB above negative full scale is applied, and R1 is trimmed to give the first transition (0000 00000000 to 000000000001 ). The a signal $11 / 2$ LSB below positive full scale is applied and R2 trimmed to give the last transition (1111 11111110 to 111111111111 ).

Figure 4. Bipolar Input Connections

## LAYOUT CONSIDERATION

Many data-acquisition components have two or more ground pins which are not connected together within the device. These "grounds" are usually referred to as the Logic Power Return, Analog Common (Analog Power Return), and Analog Signal Ground. These grounds must be tied together at one point, usually at the system power-supply ground. Ideally, a single solid ground would be desirable. However, since current flows through the ground wires and etch stripes of the circuit cards, and since these paths have resistance and inductance, hundreds of millivolts can be generated between the system ground point and the ground pin of the AD578 or AD579. Separate ground returns should be provided to minimize the current flow in the path from sensitive points to the system ground point. In this way supply currents and logic-gate return currents are not summed into the same return path as analog signals where they would cause measurement errors.

Figure 5. Basic Bypassing Practice
Each of the AD578 or AD579 supply terminals should be capacitively decoupled as close to the ADC as possible. A large value capacitor such as $10 \mu \mathrm{~F}$ in parallel with a $0.1 \mu \mathrm{~F}$ capacitor is usually sufficient. Analog supplies are bypassed to the Analog Power Return pin and the logic supply is bypassed to the Digital GND pin.
To minimize noise the reference output ( $\operatorname{Pin} 24$ ) should be decoupled by a $6.8 \mu \mathrm{~F}$ capacitor to Pin 30 .

## AD578/AD579

## CLOCK RATE CONTROL

The internal clock is preset to a nominal conversion time of $5.6 \mu \mathrm{~s}$ (AD578) or $4.8 \mu \mathrm{~s}$ (AD579). It can be adjusted for either faster or slower conversion rates. For faster conversions connect the appropriate $1 \%$ resistor between Pins 17 and 18 , and short Pin 18 to Pin 19. See Figure 6 or 7.
For slower conversions (AD578 only) connect a capacitor between Pins 15 and 17.

NOTE: No-Missing-Code operation is not guaranteed when operating in this mode if a particular grade's conversion speed specification is exceeded

Figure 6. AD578 Conversion Times vs. $R$ or $C$ Values

Figure 7. AD579 Clock Rate Control Connection

Short Cycle Input-A short cycle input, Pin 14, permits the timing cycle to be terminated after any number of desired bits has been converted, allowing shorter conversion times in applications not requiring the full 10-bit (AD579) or 12-bit (AD578) resolution. Short cycle pin connections and associated conversion times are summarized in Tables III and IV.

Table III. AD578 Short Cycle Connections

| Resolution (Bits) | 12 | 10 | 8 |
| :--- | :--- | :--- | :--- |
| Connect Pin 14 to Pin | 16 | 2 | 4 |
| Conversion Speed ( $\mu \mathrm{s}$ ) | 3 | 2.5 | 2 |

Table IV. AD579 Short Cycle Connections

| Resolution (Bits) | 10 | 8 |
| :--- | :--- | :--- |
| Connect Pin 14 to Pin | 2 | 4 |
| Conversion Speed ( $\mu \mathrm{s}$ ) | 1.8 | 1.5 |

External Clock-An external clock may be connected directly to the clock input, Pin 19. When operating in this mode, the convert start should be held high for a minimum of one clock period in order to reset the SAR and synchronize the conversion cycle. A positive going pulse width of 100 to 200 nanoseconds will provide a continuous string of conversions that start on the first rising edge of the external clock after the EOC output has gone low.

External Buffer Amplifier-In applications where the AD578 is to be driven from high impedance sources or directly from an analog multiplexer a fast slewing, wideband op amp like the AD711 should be used

Figure 8. Input Buffer
