# Low Power, High Output Current xDSL Line Driver 

 AD8016
## FEATURES

xDSL Line Driver that Features Full ADSL CO (Central Office) Performance on $\pm 12$ V Supplies and Full CPE (Customer Premise) Performance on $\pm 6$ V Supplies
Low Power Operation
$\pm 5 \mathrm{~V}$ to $\pm 12 \mathrm{~V}$ Voltage Supply
$12.5 \mathrm{~mA} / \mathrm{Amp}$ (Typ) Total Supply Current
Power-Reduced Keep-Alive Current of $4.5 \mathrm{~mA} /$ Amp
High Output Voltage and Current Drive
$I_{\text {OUT }}=600 \mathrm{~mA}$
40 V p-p Differential Output Voltage $R_{L}=50 \Omega$, $\mathrm{V}_{\mathrm{S}}= \pm 12 \mathrm{~V}$
Low Distortion
-75 dBc @ 1 MHz SFDR, $\mathrm{R}_{\mathrm{L}}=100 \Omega, \mathrm{~V}_{\mathrm{o}}=2 \mathrm{~V} \mathrm{p}-\mathrm{p}$
High Speed
78 MHz Bandwidth ( -3 dB ), G = +5
40 MHz Gain Flatness
1000 V/ $\mu \mathrm{s}$ Slew Rates
MTPR = -75 dBc, $26 \mathbf{k H z}$ to $1.1 \mathrm{MHz}, \mathrm{Z}_{\text {LINE }}=100 \Omega$, $\mathbf{P}_{\text {LINE }}=\mathbf{2 0 . 4 ~ d B m}$

## PRODUCT DESCRIPTION

The AD8016 high output current dual amplifier is designed for the line drive interface in Digital Subscriber Line systems such as ADSL, HDSL2 and proprietary xDSL systems. The drivers are capable, in full bias operation, of providing 24.4 dBm output power into low resistance loads, enough to power a 20.4 dBm line, including hybrid insertion loss.

The AD8016 is available in a low cost 24 -lead SOIC and a thermally enhanced 20-lead PSOP. Operating from $\pm 12 \mathrm{~V}$ supplies, the AD 8016 requires only 1.5 W of total power

## PIN CONFIGURATIONS

dissipation (refer to the Power Dissipation section for details) while driving 20.4 dBm of power downstream using the xDSL hybrid in Figure 44a and Figure 44b. Two digital bits (PDWN0, PDWN1) allow the driver to be capable of full performance, an output "keep-alive state," or two intermediate bias states. The "keep-alive" state biases the output transistors enough to provide a low impedance at the amplifier outputs for back termination.

The low power dissipation, high output current, high output voltage swing, flexible power-down and robust thermal packaging enable the AD8016 to be used as the Central Office (CO) or Customer Premise Equipment (CPE) terminal driver in ADSL, HDSL2, VDSL and proprietary xDSL systems.

## MAXIMUM POWER DISSIPATION

The maximum power that can be safely dissipated by the AD8016 is limited by the associated rise in junction temperature. The maximum safe junction temperature for plastic encapsulated device is determined by the glass transition temperature of the plastic, approximately $+150^{\circ} \mathrm{C}$. Temporarily exceeding this limit may cause a shift in parametric performance due to a change in the stresses exerted on the die by the package.
The output stage of the AD8016 is designed for maximum load current capability. As a result, shorting the output to common can cause the AD8016 to source or sink 2000 mA . To ensure proper operation, it is necessary to observe the maximum power derating curves. Direct connection of the output to either power supply rail can destroy the device.

Figure 3. Plot of Maximum Power Dissipation vs. Temperature for AD8016 for $T_{J}=+125^{\circ} \mathrm{C}$

## ORDERING GUIDE

| Model | Temperature <br> Range | Package <br> Description | Package <br> Option |

| AD8016ARB-EVAL | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | Evaluation Board | ARB-EVAL |

## CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD8016 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## THEORY OF OPERATION

The AD8016 is a current feedback amplifier with high ( 500 mA ) output current capability. With a current feedback amplifier the current into the inverting input is the feedback signal and the open-loop behavior is that of a transimpedance, $\mathrm{dVo} / \mathrm{dIin}$ or $\mathrm{T}_{\mathrm{Z}}$. The open-loop transimpedance is analogous to the open-loop voltage gain of a voltage feedback amplifier. Figure 37 shows a simplified model of a current feedback amplifier. Since $R_{I N}$ is proportional to $1 / \mathrm{g}_{\mathrm{m}}$, the equivalent voltage gain is just $\mathrm{T}_{\mathrm{Z}} \times \mathrm{g}_{\mathrm{m}}$, where $g_{m}$ is the transconductance of the input stage. Basic analysis of the follower with gain circuit yields:

$$
\frac{V_{O}}{V_{I N}}=G \times \frac{T_{Z}(S)}{T_{Z}(S)+G \times R_{I N}+R_{F}}
$$

where:

$$
\begin{gathered}
G=1+\frac{R_{F}}{R_{G}} \\
R_{I N}=\frac{1}{g_{m}} \approx 25 \Omega
\end{gathered}
$$

Recognizing that $G \times R_{I N} \ll R_{F}$ for low gains, the familiar result of constant bandwidth with gain for current feedback amplifiers is evident, the 3 dB point being set when $\left|\mathrm{T}_{\mathrm{Z}}\right|=\mathrm{R}_{\mathrm{F}}$. Of course, for a real amplifier there are additional poles that contribute excess phase and there will be a value for $\mathrm{R}_{\mathrm{F}}$ below which the amplifier is unstable. Tolerance for peaking and desired flatness will determine the optimum $\mathrm{R}_{\mathrm{F}}$ in each application.

Figure 37. Simplified Block Diagram
The AD8016 is the first current feedback amplifier capable of delivering 400 mA of output current while swinging to within 2 V of either power supply rail. This enables full CO ADSL performance on only 12 V rails, an immediate $20 \%$ power saving, and CPE performance on 6 V rails. The AD8016 is also
unique in that it has a power management system included onchip. It features four user programmable power levels (all of which provide a low output impedance of the driver), as well as the provision for complete shutdown (high impedance state). Also featured is a thermal shutdown with alarm signal.

## POWER SUPPLY AND DECOUPLING

The AD8016 should be powered with a good quality (i.e., low noise) dual supply of $\pm 12 \mathrm{~V}$ for the best distortion and Multitone Power Ratio (MTPR) performance. Careful attention must be paid to decoupling the power supply pins. A $10 \mu \mathrm{~F}$ capacitor located in near proximity to the AD 8016 is required to provide good decoupling for lower frequency signals. In addition, $0.1 \mu \mathrm{~F}$ decoupling capacitors should be located as close to each of the four power supply pins as is physically possible. All ground pins should be connected to a common low impedance ground plane.

## FEEDBACK RESISTOR SELECTION

In current feedback amplifiers, selection of feedback and gain resistors will have an impact on the MTPR performance, bandwidth and gain flatness. Care should be exercised in the selection of these resistors so that optimum performance is achieved. The table below shows the recommended resistor values for use in a variety of gain settings. These values are suggested as a good starting point when designing for any application.

Table I. Resistor Selection Guide

| Gain | $\mathbf{R}_{\mathbf{F}}(\boldsymbol{\Omega})$ | $\mathbf{R}_{\mathbf{G}} \mathbf{( \boldsymbol { \Omega } )}$ |
| :--- | :--- | :--- |
| +1 | 1 k | $\infty$ |
| -1 | 500 | 500 |
| +2 | 650 | 650 |
| +5 | 750 | 187 |
| +10 | 1 k | 111 |

## REDUCED BIAS AND PWDN FEATURES

The AD8016 is designed to cover both the CO and CPE ends of an xDSL application. Designing the appropriate bias level for the particular application gives the modem designer the flexibility to maximize efficiency while maintaining reasonable levels of Multitone Power Ratio (MTPR). Optimizing driver efficiency while delivering the required DMT power is accomplished with the AD8016 through the use of the on-chip power management features. Two digitally programmable logic pins, PWDN0 and PWDN1, may be used to select four different bias levels; $100 \%$, $60 \%, 40 \%$ and $25 \%$ of full quiescent power, and are available to customize your xDSL application.
The bias level can be controlled with TTL logic levels ( $1=\mathrm{HI}$ ) applied to PWDN0 and PWDN1 logic pins alone applied to, or in combination with the BIAS pin. The DGND or digital ground pin is the ground reference for PWDN0 and PWDN1 logic. In typical ADSL applications where $\pm 12 \mathrm{~V}$ or $\pm 6 \mathrm{~V}$ supplies are used, the DGND pin is connected in common with analog ground. In single supply applications, DGND may be connected to analog ground or $\mathrm{V}_{\mathrm{Cd}} / 2$. As is shown in Figure 38, an external current drawn out of the BIAS pin will shunt away a portion of the internal bias current. Figures 35 and 36 show the
relationship between this current ( $\mathrm{I}_{\text {BIAS }}$ ) and the supply current $\left(\mathrm{I}_{\mathrm{Q}}\right)$. The reduction in supply current resulting from the use of PWDN0 and PWDN1 remains proportionate to the percentages indicated above with the maximum set by the amount of net internal bias current. An external resistor or current source may be used to fix the current out of the BIAS pin to a predetermined level. Refer to Table II and Figure 39 to determine which PWDN0 and PWDN1 logic levels may apply to your design. Full shutdown, with the outputs in a high impedance state, can be accomplished by sinking approximately $250 \mu \mathrm{~A}$ from the BIAS pin. This will reduce the supply current to approximately 2 mA .
Applying logic 0 to both PWDN0 and PWDN1 pins results in poor MTPR performance. This mode of operation is intended as a "sleep" state with the output at an active low impedance.

## THERMAL SHUTDOWN

The AD8016ARB and ARP have been designed to incorporate shutdown protection against accidental thermal overload. In the event of thermal overload, the AD8016 was designed to shut down at a junction temperature of $+165^{\circ} \mathrm{C}$ and return to normal operation at a junction temperature $+140^{\circ} \mathrm{C}$ The AD8016 will continue to operate, cycling on and off, as long as the thermal overload condition remains. The frequency of the protection cycle depends on the ambient environment, severity of the thermal overload condition, the power being dissipated and the thermal mass of the PCB beneath the AD8016. When the AD8016 begins to cycle due to thermal stress, the internal shutdown circuitry draws current out of the node connected in common with the BIAS pin, while the voltage at the BIAS pin goes to the negative rail. When the junction temperature returns to $140^{\circ} \mathrm{C}$, current is no longer drawn from this node and the BIAS pin voltage returns to the positive rail. Under these circumstances, the BIAS pin can be used to trip an alarm indicating the presence of a thermal overload condition.
Figure 38 also shows two circuits for converting this signal to a standard logic level.

Figure 38. Shutdown and Alarm Circuit

## AD8016

## APPLICATIONS

The AD8016ARP and AD8016ARB dual xDSL line driver amplifiers are the most efficient xDSL line drivers available to the market today. The AD8016 may be applied in driving modulated signals including Discrete Multitone (DMT) in either direction; upstream from Customer Premise Equipment (CPE) to the Central Office (CO) and downstream from CO to CPE. The most significant thermal management challenge lies in driving downstream information from CO sites to the CPE. Driving xDSL information downstream suggests the need to locate many xDSL modems in a single CO site. The implication is that several modems will be placed onto a single printed circuit board residing in a card cage located in a variety of ambient conditions. Environmental conditioners such as fans or air conditioning may or may not be available, depending on the density of modems and the facilities contained at the CO site. To achieve long-term reliability and consistent modem performance, designers of CO solutions must consider the wide array of ambient conditions that exist within various CO sites.

## MULTITONE POWER RATIO OR MTPR

ADSL systems rely on Discrete Multitone (or DMT) modulation to carry digital data over phone lines. DMT modulation appears in the frequency domain as power contained in several individual frequency subbands, sometimes referred to as tones or bins, each of which is uniformly separated in frequency. (See Figures 1 and 2 for examples of downstream and upstream DMT signals used in evaluating MTPR performance.) A uniquely encoded, Quadrature Amplitude Modulation (QAM) signal occurs at the center frequency of each subband or tone. Difficulties will exist when decoding these subbands if a QAM signal from one subband is corrupted by the QAM signal(s) from other subbands, regardless of whether the corruption comes from an adjacent subband or harmonics of other subbands. Conventional methods of expressing the output signal integrity of line drivers, such as spurious free dynamic range (SFDR), singletone harmonic distortion or THD, two-tone Intermodulation Distortion (IMD) and 3rd order intercept (IP3) become significantly less meaningful when amplifiers are required to drive DMT and other heavily modulated waveforms. A typical xDSL downstream DMT signal may contain as many as 256 carriers (subbands or tones) of QAM signals. Multitone Power Ratio (MTPR) is the relative difference between the measured power in a typical subband (at one tone or carrier) versus the power at another subband specifically selected to contain no QAM data. In other words, a selected subband (or tone) remains open or void of intentional power (without a QAM signal) yielding an empty frequency bin. MTPR, sometimes referred to as the "empty bin test," is typically expressed in dBc , similar to expressing the relative difference between single-tone fundamentals and 2nd or 3rd harmonic distortion components.
See Figure 1 for a sample of the ADSL downstream spectrum showing MTPR results while driving +20.4 dBm of power onto a $100 \Omega$ line. Measurements of MTPR are typically made at the output (line side) of ADSL hybrid circuits. (See Figure 41a for an example of Analog Devices' hybrid schematic.) MTPR can be affected by the components contained in the hybrid circuit, including the quality of the capacitor dielectrics, voltage ratings
and the turns ratio of the selected transformers. Other components aside, an ADSL driver hybrid containing the AD 8016 can be optimized for the best MTPR performance by selecting the turns ratio of the transformers. The voltage and current demands out of the differential driver changes depending on the transformer turns ratio. The point on the curve indicating maximum dynamic headroom is achieved when the differential driver delivers both the maximum voltage and current while maintaining the lowest possible distortion. Below this point the driver has reserve current-driving capability and experiences voltage clipping while above this point the amplifier runs out of current drive capability before the maximum voltage drive capability is reached. Since a transformer reflects the secondary load impedance back to the primary side by the square of the turns ratio, varying the turns ratio changes the load across the differential driver. In the transformer configuration of Figure 44a and 44b, the turns ratio of the selected transformer is effectively doubled due to the parallel wiring of the transformer primaries within this ADSL driver hybrid. The following equation may be used to calculate the load impedance across the output of the differential driver, reflected by the transformers, from the line side of the xDSL driver hybrid. $\mathrm{Z}^{\prime}$ is the primary side impedance as seen by the differential driver; $\mathrm{Z}_{2}$ is the line impedance and N is the transformer turns ratio.

$$
Z^{\prime} \equiv \frac{Z_{2}}{(2 \times N)^{2}}
$$

Figure 39 shows the dynamic headroom in each sub band of a downstream DMT waveform verses turns ratio running at $100 \%$ and $60 \%$ of the quiescent power while maintaining -65 dBc of MTPR at $\mathrm{V}_{\mathrm{S}}= \pm 12 \mathrm{~V}$.

Figure 39. Dynamic Headroom vs. XFMR Turns Ratio, $V_{S}= \pm 12 \mathrm{~V}$

Once an optimum turns ratio is determined, the amplifier will have an MTPR performance for each setting of the power-down pins. The table below demonstrates the effects of reducing the total power dissipated by using the PWDN pins on MTPR performance when driving 20.4 dBm downstream onto the line with a transformer turns ratio of 1:1.4.

Table II. Dynamic Power Dissipation for Downstream Transmission

| PWDN1 | PWDN0 | PD (W) | MTPR |
| :--- | :--- | :--- | :--- |
| 1 | 1 | 1.454 | -78 dBc |
| 1 | 0 | 1.262 | -75.3 dBc |
| 0 | 1 | 1.142 | -57.2 dBc |
| $0^{\star}$ | 0 | 0.120 | N/A |

$\star$ This mode is quiescent power dissipation.

## GENERATING DMT

At this time, DMT-modulated waveforms are not typically menu selectable items contained within arbitrary waveform generators. Even using (AWG) software to generate DMT signals, AWGs that are available today may not deliver DMT signals sufficient in performance with regard to MTPR due to limitations in the D/A converters and output drivers used by AWG manufacturers. Similar to evaluating single-tone distortion performance of an amplifier, MTPR evaluation requires a DMT signal generator capable of delivering MTPR performance better than that of the driver under evaluation. Generating DMT signals can be accomplished using a Tektronics AWG 2021 equipped with opt 4, (12/24-Bit, TTL Digital Data Out), digitally coupled to Analog Devices AD9754, a 14-bit TxDAC, buffered by an AD8002 amplifier configured as a differential driver. See Figure 43 for schematics of a circuit used to generate DMT signals that can achieve down to -80 dBc of MTPR performance, sufficient for use in evaluating xDSL drivers. Note that the DMT waveforms available with the AD8016ARP-EVAL and AD8016ARB-EVAL boards or similar WFM files are needed to produce the necessary digital data required to drive the TxDAC from the optional TTL Digital Data output of the TEK AWG2021. Copies of these WFM files can be obtained through the Analog Devices web site. http://www.analog.com/.

## EVALUATION BOARDS

The AD8016ARP-EVAL and AD8016ARB-EVAL boards available through Analog Device provide a platform for evaluating the AD8016 in an ADSL differential line driver circuit. The board is laid out to accommodate Analog Devices two transformer line driver hybrid circuit (see Figures 44a and 44b) including line matching network, an RJ11 jack for interfacing to line simulators, transformer coupled input for single-to-differential input conversion and accommodations for the receiver function. Schematics and layout information are available for both versions of the EVAL board. Also included in the package are WFM files for use in generating 14-bit DMT waveforms. Upstream data is contained in the ...24.wfm files and downstream data in the ...128.wfm files.
These DMT modulated signals are used to evaluate xDSL products for Multitone Power Ratio or MTPR performance. The data files are used in pairs (adslu24.wfm and adsll24.wfm go together, etc.) and are loaded into Tektronics AWG2021 arbitrary waveform generator. The adslu24.wfm is loaded via the TEK AWG2021 floppy drive into Channel 1, while the adsll24.wfm is simultaneously loaded into Channel 2. The number in the file name, prefixed with " $u$," goes into CH1 or upper channel and the "l" goes into CH2 or the lower channel. 12 bits from CH 1 are combined with 2 bits from CH 2 to achieve $14-$ bit digital data at the digital outputs of the TEK 2021. The
resulting waveforms produced at the $\mathrm{AD} 9754-\mathrm{EB}$ outputs are then buffered and amplified by the AD8002 differential driver to achieve 14 -bit performance from this DMT signal source.

## POWER DISSIPATION

In order to properly size the heat sinking area for your application, it is important to consider the total power dissipation of the AD8016. The dc power dissipation for $\mathrm{V}_{\mathrm{IN}}=0$ is $\mathrm{I}_{\mathrm{Q}}(\mathrm{VCC}-$ VEE), or $2 \times \mathrm{I}_{\mathrm{Q}} \times \mathrm{V}_{\mathrm{S}}$.
For the AD8016 powered on +12 V and -12 V supplies $\left( \pm \mathrm{V}_{\mathrm{S}}\right)$, the number is 0.6 W . In a differential driver circuit (Figure 7), we can use symmetry to simplify the computation for a dc input signal.

$$
P_{D}=2 \times I_{Q} \times V_{S}+4 \times\left(V_{S}-V_{O}\right) \frac{V_{O}}{R_{L}}
$$

where
$V_{O}$ is the peak output voltage of an amplifier.
This formula is slightly pessimistic due to the fact that some of the quiescent supply current is commutated during sourcing or sinking current into the load. For a sine wave source, integration over a half cycle yields:

$$
P_{D}=2 \times I_{Q} \times V_{S}+2\left(\frac{4 V_{O} V_{S}}{\pi R_{L}}-\frac{V_{O}^{2}}{R_{L}}\right)
$$

The situation is more complicated with a complex modulated signal. In the case of a DMT signal, taking the equivalent sine wave power overestimates the power dissipation by $\sim 23 \%$. For example:

$$
\begin{gathered}
P_{\text {OUT }}=23.4 \mathrm{dBm}=220 \mathrm{~mW} \\
V_{\text {OUT }} @ 50 \Omega=3.31 \mathrm{Vrms} \\
V_{O}=2.354 \mathrm{~V}
\end{gathered}
$$

at each amplifier output, which yields a $\mathrm{P}_{\mathrm{D}}$ of 1.81 W .
Through measurement, a DMT signal of 23.4 dBm requires 1.47 W of power to be dissipated by the AD8016. Figure 40 shows the results of calculation and actual measurements detailing the relationship between the power dissipated by the AD8016 versus the total output power delivered to the back termination resistors and the load combined. A 1:2 transformer turns ratio was used in the calculations and measurements.

Figure 40. Power Dissipation vs. Output Power (Including Back Terminations). See Figure 7 for Test Circuit

## THERMAL ENHANCEMENTS AND PCB LAYOUT

There are several ways to enhance the thermal capacity of the CO solution. Additional thermal capacity can be created using enhanced PCB layout techniques such as interlacing (sometimes referred to as stitching or interconnection) of the layers immediately beneath the line driver. This technique serves to increase the thermal mass or capacity of the PCB immediately beneath the driver. (See AD8016-EVAL boards for an example of this method of thermal enhancement.) A cooling fan that draws moving air over the PCB and xDSL drivers, while not always required, may be useful in reducing the operating temperature of the die, allowing more drivers/square-inch within the CO design. The AD8016, whether in a PSOP3 (ARP) or batwing (ARB) package, can be designed to operate in the CO solution using prudent measures to manage the power dissipation through careful PCB design. The PSOP3 package is available for use in designing the highest density CO solutions. Maximum heat transfer to the PCB can be accomplished using the PSOP3 package when the thermal slug is soldered to an exposed copper pad directly beneath the AD8016. The following offers some insight into the AD8016 power dissipation and relative junction temperature, the effects of PCB size and composition on the junction-to-air thermal resistance or $\theta_{\mathrm{JA}}$.

## THERMAL TESTING

A wind tunnel study was conducted to determine the relationship between thermal capacity (i.e., printed circuit board copper area), air flow and junction temperature. Junction-to-ambient thermal resistance, $\theta_{\mathrm{JA}}$, was also calculated for the AD8016ARP and AD8016ARB packages. The AD8016 was operated in a noninverting differential driver configuration, typical of an xDSL application yet isolated from any other modem components. Testing was conducted using a 1 ounce copper board in an ambient temperature of $\sim 24^{\circ} \mathrm{C}$ over air flows of 200,150 , 100 and 50 linear feet per minute (LFM) as well as in still air. The four layer PCB was designed to maximize the area of copper on the outer two layers of the board while the inner layers were used to configure the AD8016 in a differential driver circuit. The PCB measured $3 \times 4$ inches in the beginning of the study and was progressively reduced in size to approximately $2 \times 2$ inches. The testing was performed in a wind tunnel to control air flow in units of LFM. The tunnel is approximately 11 inches in diameter.

## AIR FLOW TEST CONDITIONS

DUT Power: Typical DSL DMT signal produces about 1.5 W of power dissipation in the AD8016 package. The fully biased (PWDN0 and PWDN1 = Logic 1) quiescent current of the AD8016 is $\sim 25 \mathrm{~mA}$. A 1 MHz differential sine wave at an amplitude of 8 V p-p/amplifier into an $\mathrm{R}_{\text {LOAD }}$ of $100 \Omega$ differential ( $50 \Omega$ per side) will produce the 1.5 W of power typical in the AD8016 device. (See the Power Dissipation section for details.)
Thermal Resistance: The junction-to-case thermal resistance $\left(\theta_{\mathrm{JC}}\right)$ of the AD8016ARB or batwing package is $8.6^{\circ} \mathrm{C} / \mathrm{W}$ and the AD8016ARP or PSOP3 package is $0.86^{\circ} \mathrm{C} / \mathrm{W}$. These package specifications were used in this study to determine junction temperature based on the measured case temperature.

PCB Dimensions of a Differential Driver Circuit: Several components are required to support the AD8016 in a differential driver circuit. The PCB area necessary for these components (i.e., feedback and gain resistors, ac coupling and decoupling capacitors, termination and load resistors) dictated the area of the smallest PCB in this study, 4.7 square inches. Further reduction in PCB area, although possible, will have consequences in terms of the maximum operating junction temperature.

## EXPERIMENTAL RESULTS

The experimental data suggests that for both packages, and a PCB as small as 4.7 square inches, reasonable junction temperatures can be maintained even in the absence of air flow. The graph in Figure 41 shows junction temperature versus air flow for various dimensions of 1 ounce copper PCBs at an ambient temperature of $+24^{\circ} \mathrm{C}$ in both the ARB and ARP packages. For the worst case package, the AD8016ARB and the worst case PCB at 4.7 square inches, the extrapolated junction temperature for an ambient environment of $+85^{\circ} \mathrm{C}$ would be approximately $+132^{\circ} \mathrm{C}$ with 0 LFM of air flow. If the target maximum junction temperature of the AD 8016 ARB is $+125^{\circ} \mathrm{C}$, a 4-layer PCB with 1 oz . copper covering the outer layers and measuring 9 square inches is required with 0 LFM of air flow.
