## Am27C128 <br> 128 Kilobit (16,384 x 8-Bit) CMOS EPROM

## DISTINCTIVE CHARACTERISTICS

■ Fast access time

- 45 ns

■ Low power consumption

- $20 \mu \mathrm{~A}$ typical CMOS standby current

■ JEDEC-approved pinout
■ Single +5 V power supply

- $\pm 10 \%$ power supply tolerance available
- $100 \%$ Flashrite programming
- Typical programming time of 2 seconds

## GENERAL DESCRIPTION

The Am27C128 is a 128K-bit ultraviolet erasable programmable read-only memory. It is organized as 16 K words by 8 bits per word, operates from a single +5 V supply, has a static standby mode, and features fast single address location programming. Products are available in windowed ceramic DIP packages as well as plastic one time programmable (OTP) PDIP and PLCC packages.
Typically, any byte can be accessed in less than 45 ns , allowing operation with high-performance microprocessors without any WAIT states. The Am27C128 offers separate Output Enable ( $\overline{\mathrm{OE}}$ ) and Chip Enable ( $\overline{\mathrm{CE}}$ )

- Latch-up protected to 100 mA from -1 V to Vcc + 1 V
- High noise immunity
- Versatile features for simple interfacing
- Both CMOS and TTL input/output compatibility
- Two line control functions
- Standard 28-pin DIP, PDIP, and 32-pin PLCC packages

## BLOCK DIAGRAM

controls, thus eliminating bus contention in a multiple bus microprocessor system.
AMD's CMOS process technology provides high speed, low power, and high noise immunity. Typical power consumption is only 80 mW in active mode, and $100 \mu \mathrm{~W}$ in standby mode.
All signals are TTL levels, including programming signals. Bit locations may be programmed singly, in blocks, or at random. The Am27C128 supports AMD's Flashrite programming algorithm (100 $\mu$ s pulses) resulting in a typical programming time of 2 seconds.

## FUNCTIONAL DESCRIPTION

## Erasing the Am27C128

In order to clear all locations of their programmed contents, it is necessary to expose the Am27C128 to an ultraviolet light source. A dosage of 15 W seconds $/ \mathrm{cm}^{2}$ is required to completely erase an Am27C128. This dosage can be obtained by exposure to an ultraviolet lamp-wavelength of $2537 \AA$ —with intensity of 12,000 $\mu \mathrm{W} / \mathrm{cm}^{2}$ for 15 to 20 minutes. The Am27C128 should be directly under and about one inch from the source and all filters should be removed from the UV light source prior to erasure.

It is important to note that the Am27C128 and similar devices will erase with light sources having wavelengths shorter than $4000 \AA$. Although erasure times will be much longer than with UV sources at $2537 \AA$, exposure to fluorescent light and sunlight will eventually erase the Am27C128 and exposure to them should be prevented to realize maximum system reliability. If used in such an environment, the package window should be covered by an opaque label or substance.

## Programming the Am27C128

Upon delivery or after each erasure the Am27C128 has all 131,072 bits in the "ONE" or HIGH state. "ZEROs" are loaded into the Am27C128 through the procedure of programming.
The programming mode is entered when $12.75 \mathrm{~V} \pm$ 0.25 V is applied to the $\mathrm{V}_{\mathrm{PP}}$ pin, $\overline{\mathrm{CE}}$ is at $\mathrm{V}_{\mathrm{IL}}$, and $\overline{\mathrm{PGM}}$ is at $\mathrm{V}_{\text {IL }}$.
For programming, the data to be programmed is applied 8 bits in parallel to the data output pins.
The Flashrite algorithm reduces programming time by using $100 \mu$ s programming pulses and by giving each address only as many pulses as is necessary in order to reliably program the data. After each pulse is applied to a given address, the data in that address is verified. If the data does not verify, additional pulses are given until it verifies or the maximum is reached. This process is repeated while sequencing through each address of the Am27C128. This part of the algorithm is done at $\mathrm{V}_{\mathrm{CC}}=6.25 \mathrm{~V}$ to assure that each EPROM bit is programmed to a sufficiently high threshold voltage. After the final address is completed, the entire EPROM memory is verified at $\mathrm{V}_{\mathrm{CC}}=\mathrm{V}_{\mathrm{PP}}=5.25 \mathrm{~V}$.
Please refer to Section 6 for programming flow chart and characteristics.

## Program Inhibit

Programming of multiple Am27C128 in parallel with different data is also easily accomplished. Except for $\overline{\mathrm{CE}}$, all like inputs of the parallel Am27C128 may be common. A TTL low-level program pulse applied to an Am27C128 $\overline{\mathrm{PGM}}$ input with $\mathrm{VPP}=12.75 \mathrm{~V} \pm 0.25 \mathrm{~V}$ and
$\overline{\mathrm{CE}}$ Low will program that Am27C128. A high-level $\overline{\mathrm{CE}}$ input inhibits the other Am27C128 devices from being programmed

## Program Verify

A verify should be performed on the programmed bits to determine that they were correctly programmed. The verify should be performed with $\overline{\mathrm{OE}}$ and $\overline{\mathrm{CE}}$ at $\mathrm{V}_{\mathrm{IL}}, \overline{\mathrm{PGM}}$ at $\mathrm{V}_{\mathrm{IH}}$, and $\mathrm{V}_{\mathrm{PP}}$ between 12.5 V and 13.0 V .

## Auto Select Mode

The auto select mode allows the reading out of a binary code from an EPROM that will identify its manufacturer and type. This mode is intended for use by programming equipment for the purpose of automatically matching the device to be programmed with its corresponding programming algorithm. This mode is functional in the $25^{\circ} \mathrm{C} \pm 5^{\circ} \mathrm{C}$ ambient temperature range that is required when programming the Am27C128.

To activate this mode, the programming equipment must force $12.0 \mathrm{~V} \pm 0.5 \mathrm{~V}$ on address line A 9 of the Am27C128. Two identifier bytes may then be sequenced from the device outputs by toggling address line $A 0$ from $V_{I L}$ to $\mathrm{V}_{\mathrm{IH}}$. All other address lines must be held at $\mathrm{V}_{\text {IL }}$ during auto select mode.

Byte $0\left(\mathrm{~A} 0=\mathrm{V}_{\mathrm{IL}}\right)$ represents the manufacturer code, and byte $1\left(\mathrm{~A} 0=\mathrm{V}_{\mathrm{IH}}\right)$, the device code. For the Am27C128, these two identifier bytes are given in the Mode Select Table. All identifiers for manufacturer and device codes will possess odd parity, with the MSB (DQ7) defined as the parity bit.

## Read Mode

The Am27C128 has two control functions, both of which must be logically satisfied in order to obtain data at the outputs. Chip Enable ( $\overline{\mathrm{CE}})$ is the power control and should be used for device selection. Output Enable ( $\overline{\mathrm{OE}}$ ) is the output control and should be used to gate data to the output pins, independent of device selection. Assuming that addresses are stable, address access time ( $t_{A C C}$ ) is equal to the delay from $\overline{\mathrm{CE}}$ to output ( $\mathrm{t}_{\mathrm{CE}}$ ). Data is available at the outputs toe after the falling edge of $\overline{\mathrm{OE}}$, assuming that $\overline{\mathrm{CE}}$ has been LOW and addresses have been stable for at least $t_{A C c}-t_{0 E}$.

## Standby Mode

The Am27C128 has a CMOS standby mode which reduces the maximum $\mathrm{V}_{\text {cc }}$ current to $100 \mu \mathrm{~A}$. It is placed in CMOS-standby when $\overline{\mathrm{CE}}$ is at $\mathrm{V}_{\mathrm{cc}} \pm 0.3 \mathrm{~V}$. The Am27C128 also has a TTL-standby mode which reduces the maximum $\mathrm{V}_{\text {cc }}$ current to 1.0 mA . It is placed in TTL-standby when $\overline{\mathrm{CE}}$ is at $\mathrm{V}_{\mathrm{IH}}$. When in standby mode, the outputs are in a high-impedance state, independent of the $\overline{\mathrm{OE}}$ input.

## Output OR-Tieing

To accommodate multiple memory connections, a twoline control function is provided to allow for:

- Low memory power dissipation

■ Assurance that output bus contention will not occur It is recommended that $\overline{\mathrm{CE}}$ be decoded and used as the primary device-selecting function, while $\overline{O E}$ be made a common connection to all devices in the array and connected to the READ line from the system control bus. This assures that all deselected memory devices are in low-power standby mode and that the output pins are only active when data is desired from a particular memory device.

## System Applications

During the switch between active and standby conditions, transient current peaks are produced on the rising and falling edges of Chip Enable. The magnitude of these transient current peaks is dependent on the output capacitance loading of the device. At a minimum, a $0.1-\mu \mathrm{F}$ ceramic capacitor (high frequency, low inherent inductance) should be used on each device between $\mathrm{V}_{\mathrm{Cc}}$ and $\mathrm{V}_{\mathrm{SS}}$ to minimize transient effects. In addition, to overcome the voltage drop caused by the inductive effects of the printed circuit board traces on EPROM arrays, a $4.7-\mu \mathrm{F}$ bulk electrolytic capacitor should be used between $V_{c c}$ and $V_{\text {ss }}$ for each eight devices. The location of the capacitor should be close to where the power supply is connected to the array.

## MODE SELECT TABLE

| Mode Pins |  | $\overline{C E}$ | $\overline{O E}$ | $\overline{\text { PGM }}$ | A0 | A9 | $V_{\text {PP }}$ | Outputs |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

|  | Device Code | VIL | VIL | X | VIH | VH | X | 16H |

## Notes:

1. $V H=12.0 \mathrm{~V} \pm 0.5 \mathrm{~V}$
2. $X=$ Either $V_{I H}$ or $V_{I L}$
3. $A 1-A 8=A 10-A 12=V$ IL, $A 13=X$
4. See DC Programming Characteristics for VPP voltage during programming.

## ABSOLUTE MAXIMUM RATINGS

Storage Temperature
OTP Products . . . . . . . . . . . . . . . $-65^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
All Other Products . . . . . . . . . . . . $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$
Ambient Temperature
with Power Applied . . . . . . . . . . . . . $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
Voltage with Respect To Vss
All pins except A9, $\mathrm{V}_{\mathrm{pp}}, \mathrm{V}_{\mathrm{cc}} .-0.6 \mathrm{~V}$ to $\mathrm{Vcc}+0.5 \mathrm{~V}$
A9 and $\mathrm{V}_{\mathrm{PP}} \ldots . . . . . . . . . .$.
VCc . . . . . . . . . . . . . . . . . . . . . -0.6 V to +7.0 V
Notes:

1. Minimum $D C$ voltage on input or I/O pins is -0.5 V . During transitions, the inputs may overshoot Vss to-2.0 V for periods of up to 20 ns . Maximum DC voltage on input and I/O pins is VCc +0.5 V which may overshoot to $V C C+2.0 \mathrm{~V}$ for periods up to 20 ns .
2. For $A 9$ and $V_{P P}$ the minimum $D C$ input is -0.5 V. During transitions, A9 and VPP may overshoot VSs to -2.0 V for periods of up to 20 ns . A9 and VPP must not exceed 13.5 V for any period of time.

Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure of the device to absolute maximum rating conditions for extended periods may affect device reliability.

## OPERATING RANGES
