Advance Information

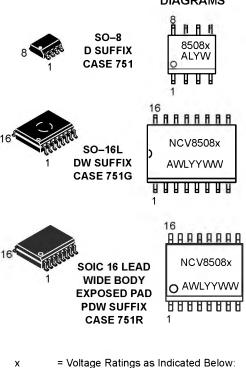

Low Dropout Linear Regulators with Watchdog, RESET, and Wake Up

The NCV8508 is a precision micropower voltage regulator family. The part contains many of the required operational requirements for powering microprocessors. Its robustness makes it suitable for severe automotive environments. The devices low dropout voltage ensures operation of loads (i.e. microprocessors) when the battery voltage is low such as during the cranking cycle of an automobile. In addition to being a good fit for the automotive environment, the NCV8508 is ideal for use in battery operated, microprocessor controlled equipment because of its extremely low quiescent current.

Features

- Output Voltage Options: 3.3 V or 5.0 V
- ±3.0% Output Voltage
- I_{OUT} Up to 250 mA
- Quiescent Current Independent of Load
- Micropower Compatible Control Functions:
 - Wake Up
 - Watchdog
 - RESET
- Low Dropout Voltage
- Low Quiescent Current (100 µA typ)
- Protection Features:
 - Thermal Shutdown
 - Short Circuit
 - 45 V Operation
- Internally Fused Leads in SO-16L Package

3 = 3.3 V 5 = 5.0 V

- = Assembly Location
- WL, L = Wafer Lot
- YY, Y = Year
- VWV, W = Work Week

ORDERING INFORMATION

DEFINITION OF TERMS

Dropout Voltage: The input–output voltage differential at which the circuit ceases to regulate against further reduction in input voltage. Measured when the output voltage has dropped 100 mV from the nominal value obtained at 14 V input, dropout voltage is dependent upon load current and junction temperature.

Input Voltage: The DC voltage applied to the input terminals with respect to ground.

Line Regulation: The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques

such that the average chip temperature is not significantly affected.

Load Regulation: The change in output voltage for a change in load current at constant chip temperature.

Quiescent Current: The part of the positive input current that does not contribute to the positive load current. The regulator ground lead current.

Ripple Rejection: The ratio of the peak–to–peak input ripple voltage to the peak–to–peak output ripple voltage.

Current Limit: Peak current that can be delivered to the output.

DETAILED OPERATING DESCRIPTION

The NCV8508 is a precision micro-power voltage regulator with very low quiescent current (100 μ A typical at 250 mA load). A typical dropout voltage is 425 mV at 150 mA. Microprocessor control logic includes Watchdog,

Wake Up and RESET. This unique combination of extremely low quiescent current and full microprocessor control makes the NCV8508 ideal for use in battery

operated, microprocessor controlled equipment in addition to being a good fit in the automotive environment.

The NCV8508 Wake Up function brings the microprocessor out of Sleep mode. The microprocessor in turn, signals its Wake Up status back to the NCV8508 by issuing a Watchdog signal.

The Watchdog logic function monitors an input signal (WDI) from the microprocessor. The NCV8508 responds to the falling edge of the Watchdog signal which it expects at least once during each wake–up period. When the correct Watchdog signal is received, a falling edge is issued on the wake–up signal line.

RESET is independent of V_{IN} and operates correctly to an output voltage as low as 1.0 V. A signal is issued in any of three situations. During power up the RESET is held low until the output voltage is in regulation. During operation if

the output voltage shifts below the regulation limits, the $\overline{\text{RESET}}$ toggles low and remains low until proper output voltage regulation is restored. And finally, a $\overline{\text{RESET}}$ signal is issued if the regulator does not receive a Watchdog signal within the Wake Up period.

The $\overrightarrow{\text{RESET}}$ pulse width. Wake Up signal frequency, and Wake Up delay time are all set by one external resistor, R_{Delav} .

The Delay pin is a buffered bandgap voltage (1.25 V). It can be used as a reference for an external tracking regulator like the CS8182.

The regulator is protected against short circuit and thermal runaway conditions. The device runs through 45 volt transients. making it suitable for use in automotive environments.

CIRCUIT DESCRIPTION

Functional Description

To reduce the drain on the battery a system can go into a low current consumption mode when ever its not performing a main routine. The Wake Up signal is generated continuously and is used to interrupt a microcontroller that is in sleep mode. The nominal output is a 5.0 volt square wave with a duty cycle of 50% at a frequency that is determined by a timing resistor. R_{Delay} .

When the microprocessor receives a rising edge from the Wake Up output, it must issue a watchdog pulse and check its inputs to decide if it should resume normal operations or remain in the sleep mode.

The first falling edge of the watchdog signal causes the Wake Up to go low within 2.0 μ s (typ) and remain low until the next Wake Up cycle (see Figure 15). Other watchdog pulses received within the same cycle are ignored (Figure 3).

During power up, $\overline{\text{RESET}}$ is held low until the output voltage is in regulation. During operation, if the output voltage shifts below the regulation limits, the $\overline{\text{RESET}}$ toggles low and remains low until proper output voltage regulation is restored. After the $\overline{\text{RESET}}$ delay, $\overline{\text{RESET}}$ returns high.

The Watchdog circuitry continuously monitors the input watchdog signal (WDI) from the microprocessor. The absence of a falling edge on the Watchdog input during one Wake Up cycle will cause a RESET pulse to occur at the end of the Wake Up cycle. (see Figure 4).

The Wake Up output is pulled low during a $\overline{\text{RESET}}$ regardless of the cause of the $\overline{\text{RESET}}$. After the $\overline{\text{RESET}}$ returns high, the Wake Up cycle begins again (see Figure 4).

The $\overline{\text{RESET}}$ Delay Time. Wake Up signal frequency and $\overline{\text{RESET}}$ high to Wake Up delay time are all set by one external resistor R_{Delay} .

Wake Up period = $(4.17 \times 10^{-7})R_{Delay}$ RESET Delay Time = $(5.21 \times 10^{-8})R_{Delay}$ RESET HIGH to Wake Up Delay Time = $(2.08 \times 10^{-7})R_{Delay}$ Capacitor temperature coefficient and tolerance as well as the tolerance of the NCV8508 must be taken into account in order to get the correct system tolerance for each parameter.

APPLICATION NOTES

Calculating Power Dissipation in a Single Output Linear Regulator

The maximum power dissipation for a single output regulator (Figure 17) is:

$$PD(max) = [VIN(max) - VOUT(min)]^{I}OUT(max)$$
(1)
+ VIN(max)^{I}Q

where:

 $V_{IN(max)}$ is the maximum input voltage.

V_{OUT(min)} is the minimum output voltage,

 $I_{\mbox{OUT}(\mbox{max})}$ is the maximum output current for the application, and

 I_Q is the quiescent current the regulator consumes at $I_{OUT(max)}.$

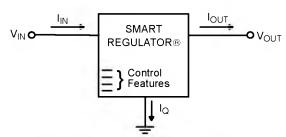

Figure 17. Single Output Regulator with Key Performance Parameters Labeled

Once the value of $P_{D(max)}$ is known, the maximum permissible value of $R_{\Theta JA}$ can be calculated:

$$R_{\Theta JA} = \frac{150^{\circ}C - T_{A}}{P_{D}}$$
(2)

The value of $R_{\Theta JA}$ can then be compared with those in the package section of the data sheet. Those packages with $R_{\Theta JA}$'s less than the calculated value in equation 2 will keep the die temperature below 150°C.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Heat Sinks

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $R_{\Theta JA}$:

$$R_{\Theta JA} = R_{\Theta JC} + R_{\Theta CS} + R_{\Theta SA}$$
(3)

where:

 $R_{\Theta JC}$ = the junction–to–case thermal resistance.

 $R_{\Theta CS}$ = the case-to-heatsink thermal resistance, and

 $R_{\Theta SA}$ = the heatsink-to-ambient thermal resistance.

 $R_{\Theta JC}$ appears in the package section of the data sheet. Like $R_{\Theta JA}$, it too is a function of package type. $R_{\Theta CS}$ and $R_{\Theta SA}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.
